

# Electrophysiological Changes Across Two Days of Reading – Prediction Updating, or Memory Retrieval?

Ryan J. Hubbard & Kara D. Federmeier  
University of Illinois, Urbana-Champaign

## Introduction

- When comprehending language, people predict features of upcoming words to facilitate processing
- Unexpected but plausible words elicit different neural responses (ERPs) from semantically anomalous words
- This may reflect updating of predictions vs. a failure to update the event structure (Kuperberg et al., 2020)

## The Present Study

We examined prediction updating in a 2-day reading study, in which participants read sentences with expected or unexpected / anomalous endings (violations) on 2 separate days. We examined changes in ERP responses across days to determine if different types of prediction violations lead to different levels of prediction updating.

## Methods

- Study Design**
- 35 participants
  - Read sentences for memory test
  - Switch items created by replacing the violating ending with the expected ending
  - Recognition memory test on sentence endings on Day 2
- EEG Setup**
- 26 scalp channels, mastoids reference
  - Bandpass filtered, 0.1-20 Hz
  - Ocular artifacts corrected w/ ICA
  - 200 ms pre-stimulus baseline
  - Time-locked to onset of sentence ending word

Day 1 Stimuli	
Strong Constraint, Expected (SCE)	I could not remember his <b>name</b> .
Weak Constraint, Expected (WCE)	Tim's friend pushed him into a <b>pool</b> .
Strong Constraint, Unexpected (SCU)	He made a holster for his <b>father</b> .
Strong Constraint, Anomalous (SCA)	The rude waiter was not given a <b>cabin</b> .

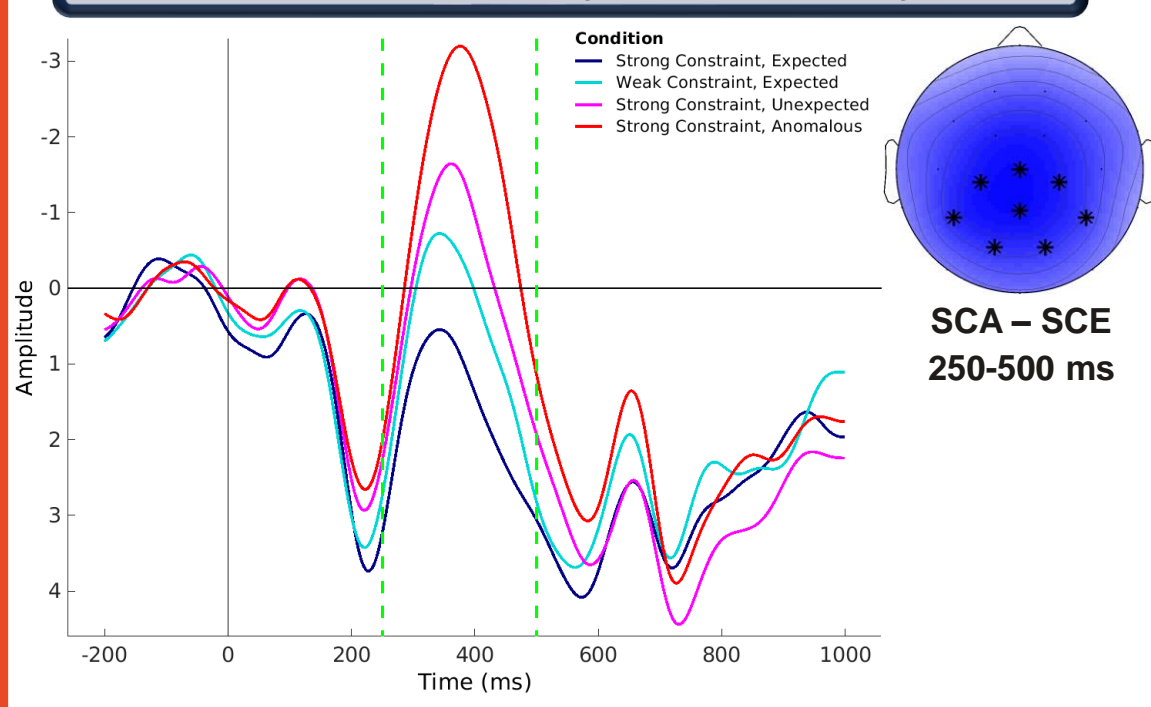

Day 2 Stimuli	
SCE, Repeat (SCE)	I could not remember his <b>name</b> .
WCE, Repeat (WCE)	Tim's friend pushed him into a <b>pool</b> .
SCU, Repeat (SCU)	He made a holster for his <b>father</b> .
SCU, Switch (SCU)	He made a holster for his <b>gun</b> .
SCA, Repeat (SCA)	The rude waiter was not given a <b>cabin</b> .
SCA, Switch (SCA)	The rude waiter was not given a <b>tip</b> .

## Day 1 ERP Results

### Frontal Positivity to Unexpected Endings

### Graded N400 by Predictability

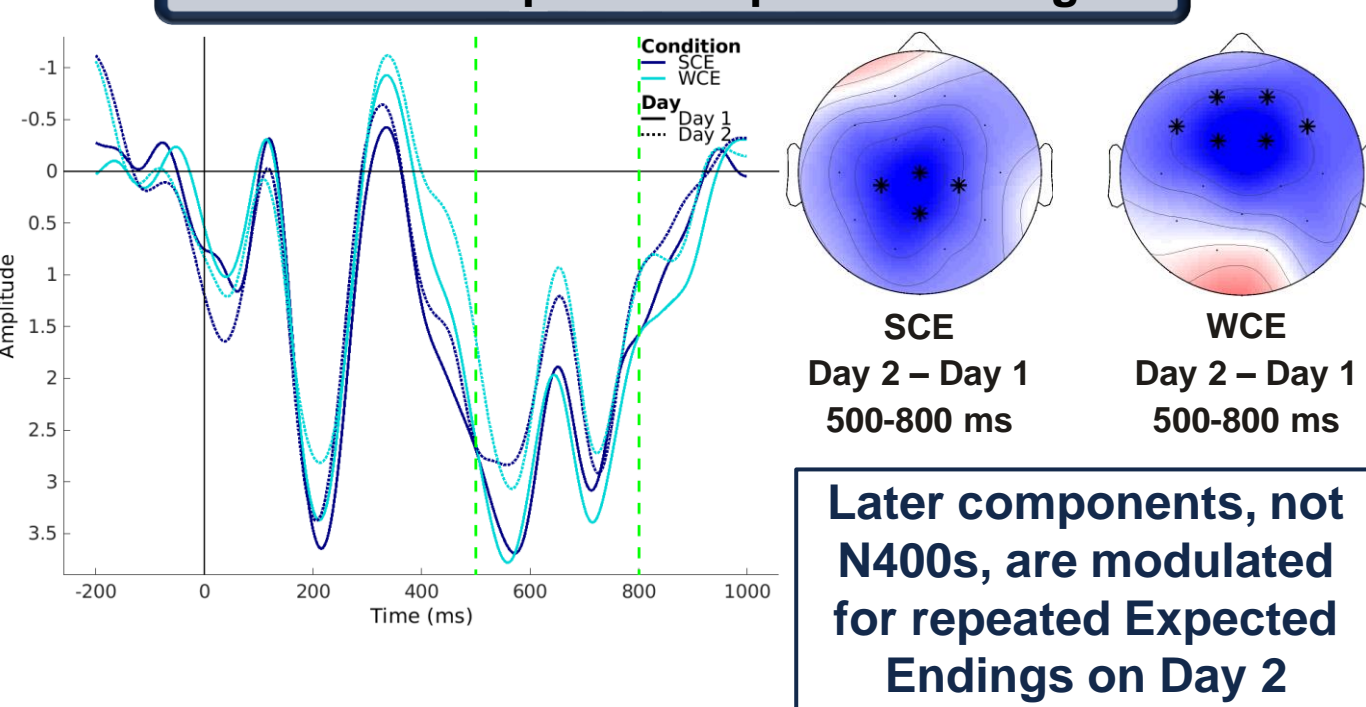

### Posterior Positivity to Anomalous Endings

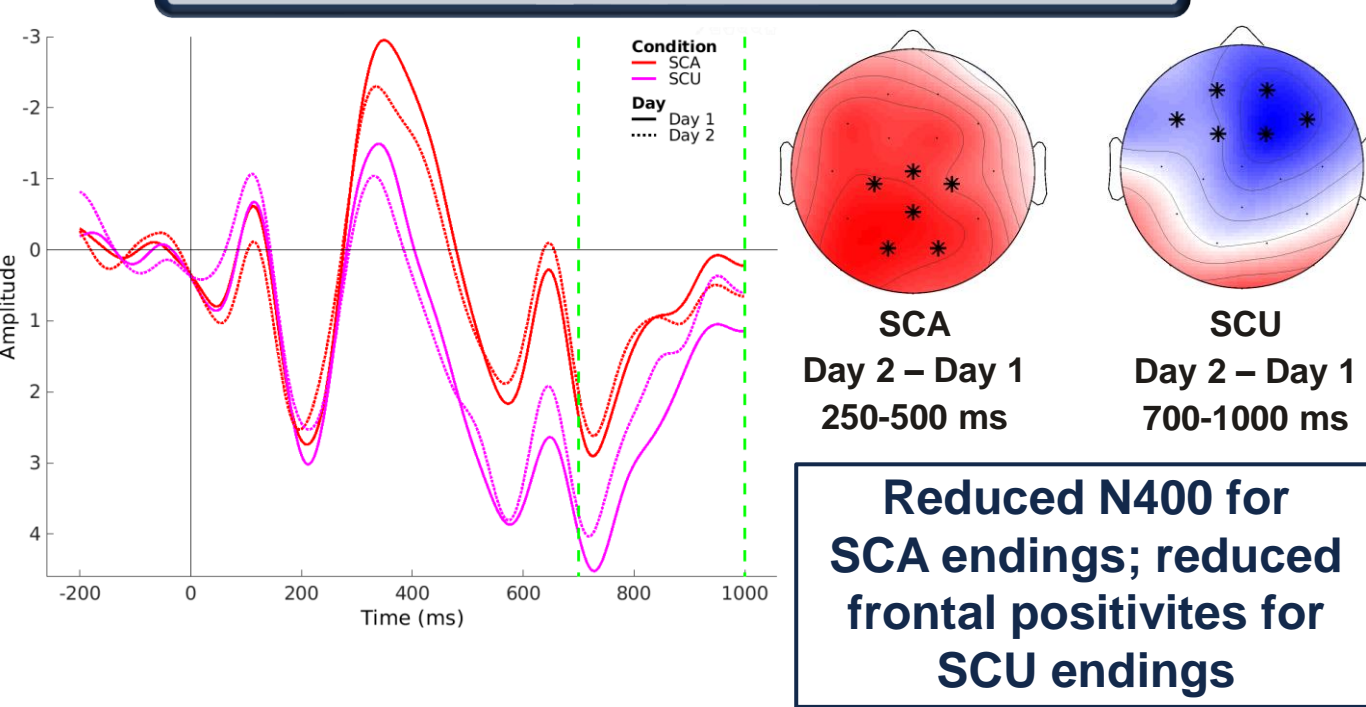

## Day 2 ERP Results

### ERPs to Repeated Expected Endings

Later components, not N400s, are modulated for repeated Expected Endings on Day 2

### ERPs to Repeated Violations

Reduced N400 for SCA endings; reduced frontal positivites for SCU endings

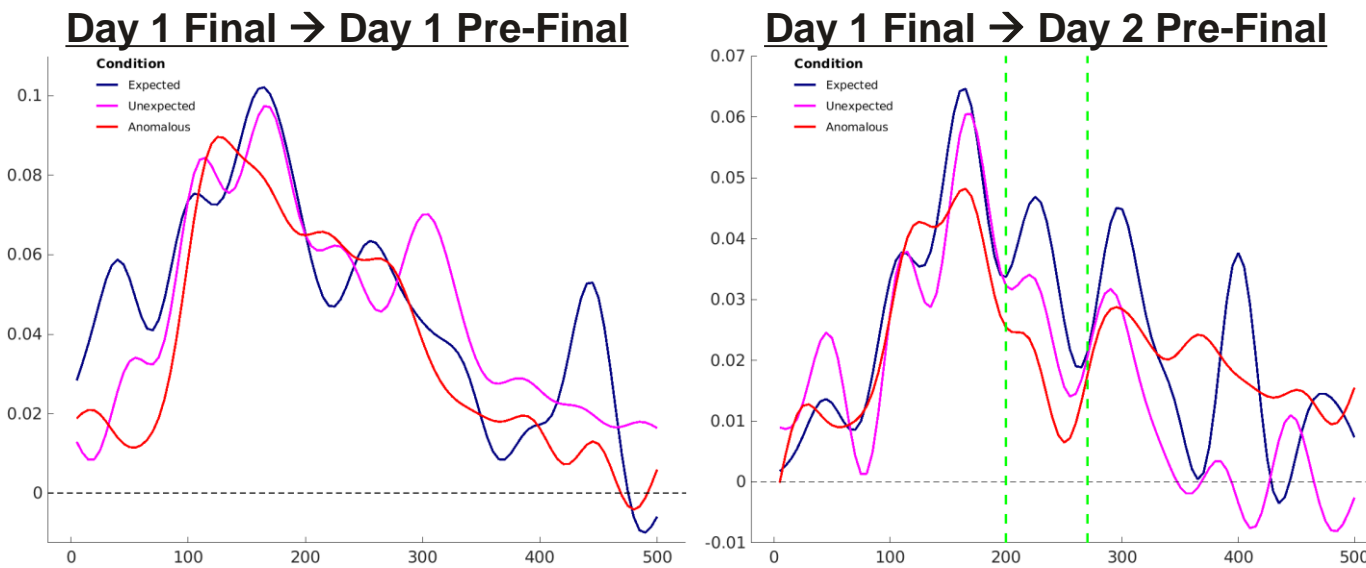

### ERPs to Violation Switch Endings

SCU-Switch endings elicit late frontal negativities; SCA-Switch endings do not

## Day 2 RSA Results

### RSA Examining Pre-Activation

Greater neural similarity for Expected Endings  
Pattern of neural similarity did not change across days for prediction violations

### RSA of Repeated Endings

Reduced similarity across days for Expected Endings  
Pattern of neural similarity did not largely differ for prediction violations

## Conclusions

- Expected endings to on Day 2 did not elicit reduced N400 amplitudes, but later responses were modulated, potentially more in line with memory for the words rather than prediction
- Repeated anomalous endings elicited reduced N400s, whereas repeated unexpected endings elicited reduced frontal positivity responses; potentially some reduction in revision specifically for unexpected endings
- Only SCU-Switch endings elicited a frontal negativity response, similar to effects observed when reinterpretation is necessary; more evidence of revision specifically for unexpected endings
- Results from RSA were inconsistent with a change in predictive pre-activation of words that were previously unexpected; however, later processes, potentially reflecting memory or revision, could differ
